1 How to get the IP address of a local client

Symptom

Due to the complexity and diversity of the network, the user may not be able to correctly locate the IP address of the local client which should be add in the instance whitelist. This article describes how to view the IP of a local client.

Here is an example to denote the detailed steps of the operation.

Procedure

- 1. Add 0 . 0 . 0 . 0 / 0 to the whitelist of the AnalyticDB for PostgreSQL instance.
 - a. Log on to the AnalyticDB for PostgreSQL console.
 - b. Select the region where the target instance is located.
 - c. Click the ID of the instance to go to the Basic Information page of the instance.
 - d. In the left-side navigation pane, click Security Controls.
 - e. In the Whitelist Settings page, click Modify under the default whitelist group to go to the Modify Group page.
 - f. Delete the default address 127.0.0.1 from the whitelist and then add 0.0.0
 0 / 0 to the whitelist.

Note:

The 0.0.0.0/0 address which allows any IP to access the database involves a high security risk, and this configuration should be deleted as soon as possible.

g. Click OK to finish the operation.

2. Connect to the AnalyticDB for PostgreSQL instance using a local client. See *Connect* to a *HybridDB for PostgreSQL database* to download and install the psql client. Issue the following statement to connect to the database:

```
psql - h yourgpdbad dress .gpdb .rds .aliyuncs .com - p
3432 - d postgres - U gpdbaccoun t
```

Parameter descriptions are as follows:

- \cdot -h: specifies the host address.
- -p: specifies the port number.
- · -d: specifies the database (the default database is postgres).
- · -U: specifies the connected user.

You can view more parameters by performing psql -- help. And in the psql prompt, you can view more supported psql commands by performing \?.

3. Run the following statement in the SQL command line window in the database to query the IP address of the local client.

select * from pg_stat_ac tivity;

The value in the CLIENT_ADD R of the query result is the IP address of the local client.

<pre>postgres=> select * from pg_stat_activity; datid datname procpid sess_id usesysid usename current_qu ery waiting query_start backend_start client_addr client_port application_name xact_start waiting_reason</pre>	
++++++	
10902 postgres 45909 254025 17239 test123 select * from pg_st at_activity; f 2019-02-19 14:07:00.37242+08 2019-02-19 14:06:26.1704 67+08 105.11.54.5 31964 psql 2019-02-19 14:07:00.37242 +08 (1 row) 109.02 109.02 109.02 109.02 109.02	
postgres=>	

4. Remove 0 . 0 . 0 . 0 / 0 from the whitelist, and add the IP address in the previous step to access the database with a client.

2 How to view the data size of a table or a database?

Suppose that the table schema is < schemaname > and the table name is < tablename >.

• Run the following command to query the total size of a table (unit: MB, including the table index and data):

```
select pg_size_pr etty ( pg_total_r elation_si ze ('<
schemaname >.< tablename >'));
```

• Run the following command to query the data size of a table (unit: MB, excluding the index):

```
select pg_size_pr etty ( pg_relatio n_size ('< schemaname >.<
tablename >'));
```

• Run the following command to query the total size of all the partitions in a partition table (unit: MB, including the table index and data):

```
select schemaname , tablename , round ( sum ( pg_total_r
elation_si ze ( schemaname || '.' || partitiont ablename ))/
1024 / 1024 ) " MB " from pg_partiti ons where schemaname
='< schemaname >' and tablename ='< tablename >' group by 1
, 2;
```

• Run the following command to query the total size of all the tables under a schema (unit: MB, including the index and data):

```
select schemaname , round ( sum ( pg_total_r elation_si ze (
schemaname ||'.'|| tablename ))/ 1024 / 1024 ) " Size_MB " from
pg_tables where schemaname ='< schemaname >' group by 1;
```

• Run the following command to query the size of each database (unit: MB):

```
select datname , pg_size_pr etty ( pg_databas e_size ( datname
)) from pg_databas e ;
```

3 What ETL tools does AnalyticDB for PostgreSQL currently support? How to synchronize data from other data sources to AnalyticDB for PostgreSQL on a regular basis?

The following ETL tools are supported:

- Alibaba Cloud Data Integration: an ETL tool provided by Alibaba Cloud. In Data Integration, you can configure AnalyticDB for PostgreSQL as a PostgreSQL database to synchronize data from other data sources (RDS, MaxCompute, and TableStore) to AnalyticDB for PostgreSQL.
 - You can directly read data from other data sources, and write data to AnalyticDB for PostgreSQL.
 - If the data size is big and concurrent imports are required, we recommend that you first import the data to OSS from other data sources by using Data Integratio n, and then import the data by using the OSS external table to AnalyticDB for PostgreSQL.
- · Pentaho Kettle: an open-source ETL tool.
 - You can import data through Kettle to an ephemeral disk first, and then import the data to AnalyticDB for PostgreSQL by using COPY or OSS.
 - You can also mount an OSS instance as a virtual ephemeral disk, import data through Kettle to that disk, and then import data to AnalyticDB for PostgreSQL by using the OSS external table.
- · Informatica: a commercial ETL tool.
- *Bifrost*: an ETL tool in Alibaba Cloud marketplace. It now provides commercial services.
- *dbsync*: an open-source database synchronization tool provided by Alibaba Cloud.
 - Supports synchronizing data concurrently from MySQL and PostgreSQL to AnalyticDB for PostgreSQL.
 - Supports simple data conversion.
 - Supports parsing binlog to synchronize data from MySQL to AnalyticDB for PostgreSQL in a quasi-real-time manner.

4 How to learn more technical information?

You can learn more technical information from the *open-source community of Greenplum Database*. In addition, you can contact us by using the ticket system.

5 How to select an instance type?

When creating or upgrading an instance in AnalyticDB for PostgreSQL, you must specify the group type and number of groups.

AnalyticDB for PostgreSQL supports multiple group types. For more information, see *Instance types*. You can also specify multiple groups with the same type. We recommend that you consider the following factors when selecting your group type and quantity:

- The storage space required
- The computing capability required

Storage space

The storage space of a group type and group quantity combo = the storage space of the group type * the number of groups.

Note the following when determining the expected storage space:

- Make the storage space slightly larger than the actual space evaluated. Because data processing can generate some logs and temporary files.
- Select distribution keys appropriately and avoid data skews. Allocate the distributi
 on keys evenly as much as possible, otherwise data skews may occur. Data skews
 can exhaust the storage space in a computing group and leave the storage space of
 other groups idle, resulting in low usage of storage resource.

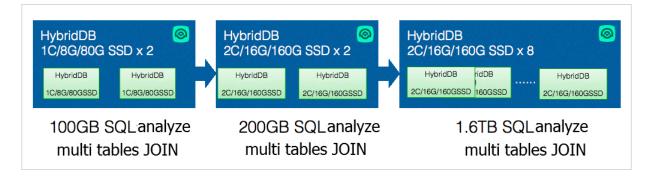

Computing capability

A group type and group quantity combo matches a specific computing capability. The computing capability is determined by the computing group type, number of CPUs, memory size, and the number of groups.

AnalyticDB for PostgreSQL has two group types available:

- High-performance group: the group type name starts with gpdb.group.segsdx. This type features a better I/O capability that secures higher performance.
- High-capacity group: the group type name starts with gpdb.group.seghdx. This type features a larger and more affordable space to meet higher storage demands.

Three other factors also contribute to linear increase of performance. Take a high -performance type for example. The SQL execution durations in the following use cases are close to each other:

In addition, you also need to take the price into account.

6 How to clear the data on a locked disk?

Analysis

When the disk space of any computing group reaches the limit or the disk space on a master node reaches the limit, the entire instance is locked. Connect to the database and run the following command to check whether your instance is locked:

```
show rds_force_ trans_ro_n on_sup ;
```

If the rds_force_ trans_ro_n on_sup value is on in the response, it means that the instance is locked, and the database is read-only.

Fix

When an instance is locked because the disk is full, the truncate, drop, and grant operations are still supported on the data table. You can use these operations to clear the disk until the space falls within the threshold. After that, the instance is automatically unlocked in about five minutes.

Note:

Deletion is not supported when the instance is locked. Because deletion requests writing data to the xlog, which can increase space usage.

You can also run the following statement to query the table size:

select pg_size_pr etty (pg_total_r elation_si ze (' test '));

7 How do I modify parameters?

At present, AnalyticDB for PostgreSQL does not support global changes of parameters . But you can modify parameters in a connection (see Greenplum's parameter modification restrictions for details).

You can use the command alter role set = modify the parameters. This modification only applies to the specified user.

8 How to use table partition?

We recommend that you enable table partition for fact tables or large tables in the database. Table partition simplies the deleting data and importaning data operations on a regular basis. With table partition,

- You can use the alter table drop partition command to delete all the data in a partition.
- You can use partition exchange, that is, the alter table exchange partition command to add a new data partition.

AnalyticDB for PostgreSQL supports range partition, list partition, and composite partition. But range partition only supports partitioning by number or time-based fields.

An example table using range partitions is shown as follows.

```
TABLE
CREATE
                  LINEITEM
                             (
                              NULL ,
L ORDERKEY
             BIGINT
                       NOT
                             NULL ,
L PARTKEY
                       NOT
             BIGINT

                    ' 1
       ( INTERVAL
                           month ' ));
```

9 How to enable column-store and compression in AnalyticDB for PostgreSQL?

Row-store with no compression is used by default when you create a table in AnalyticDB for PostgreSQL. To enable column-store and compression, you must specify the column-store and compression options when creating the table. For example, you can add the following statement to the tabulation statements to enable the two features.

```
with ( APPENDONLY = true , ORIENTATIO N = column , COMPRESSTY PE
= zlib , COMPRESSLE VEL = 5 , BLOCKSIZE = 1048576 , OIDS = false
)
```

In general, we recommend that you enable column-store and compression, especially when you have a lot of complicated queries to the table, or when you want to reduce the storage cost.

Note:

AnalyticDB for PostgreSQL currently only supports the zlib and RLE_TYPE compression algorithms. If you specify to use quicklz, AnalyticDB for PostgreSQL automatically converts the algorithm to zlib.
